

Flat claim -> scoped theorem -> evidence-backed audit

1 FLATTENED CLAIM

"Join queries can be evaluated efficiently in parallel."

The sentence hides the conditions that determine what is proved.

query?

model?

rounds?

?

extract

2 SCOPED THEOREM RECORD

PAC Theorem 14

full conjunctive join

MPC, 3 rounds

per-server load

high probability

roles: q fixed | D input | p,r,S parameters
unknown axes remain UNKNOWN until evidence is found

bind

3 EVIDENCE CHECK

source pointer

Theorem 14 | PDF p.12 | Section 5
version:0f48322c4246924097bc
SHA-256: 848f00c3...595cf

[OK] scope [OK] bound [OK] probability

promotion is allowed only after exact review

4 WHAT THE FLAT SENTENCE DROPS

scope axes

query fragment: $\text{Fragment}(D, r, C)$

assumptions: C adheres to spectrum r

solution: S solves q with respect to C

resource: $O\sim(|D|/p^{1/c(S)})$ per server

semantics: three rounds, high probability

identity: ICDT 2025 version + source hash

field-level audit and promotion

extract candidate fields with uncertainty

locate label, page, section, span, hash

review check scope against exact source version

promote sign record or retain explicit UNKNOWN

flat wording is a search cue, never the theorem record

lost conditions = unsafe generalization

exact evidence = bounded promotion

a theorem is a scoped, versioned, evidence-bound object
